# 1 The only section

- We use bibtex for references (e.g. Freyaldenhoven et al. [2019]).
- Ideally all numbers should be softcoded, and come directly from output. For example, in our baseline simulations setup, where we simulate the throw of two 6-sided dice, the average sum of the two throws is equal to 7.02. That way all numbers are by construction always up-to-date.
- Below, Figure 1 includes a histogram of the simulation exercise.

**Figure 1:** Numerical frequency for the sum of two six-sided die. Figure based on 500 throws.

We also include a second simulation for an 8-sided dice, where the average sum of the two throws is equal to 9.07. The corresponding histogram is depicted in Figure 2

**Figure 2:** Numerical frequency for the sum of two eight-sided die. Figure based on 500 throws.

This is Figure 6 with both of the previous figures as subplots.

These are figures measuring the number of rolls by the current (total) sum over time. ??

We also include a second simulation for an 8-sided dice. The corresponding scatterplot is depicted in Figure ??

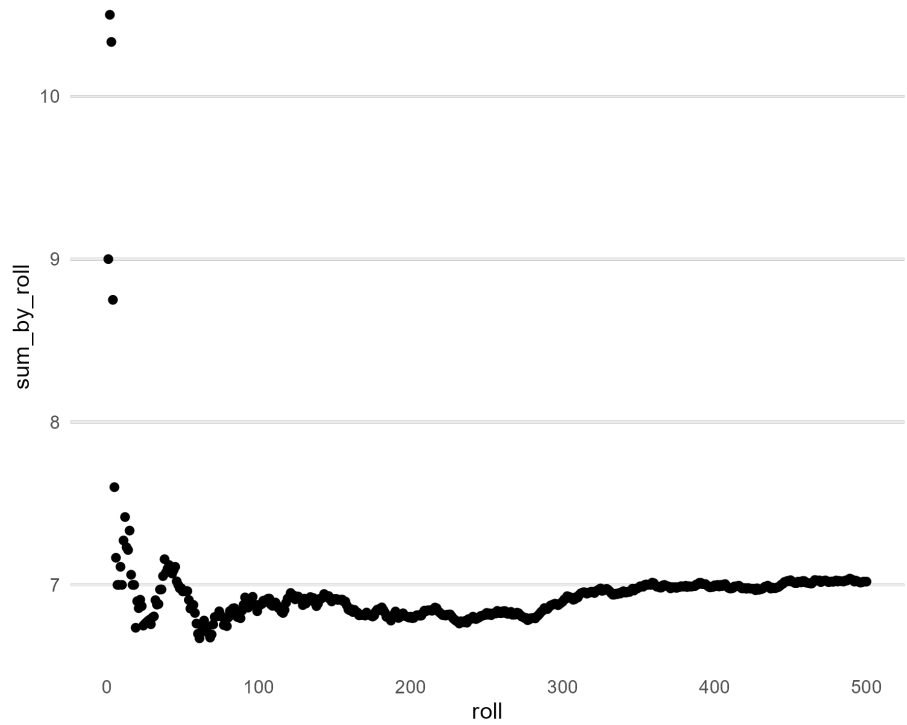

This is Figure 6 with both of the previous scatterplots as subplots.

Finally, we add a scatter plot from an exemplary do file in Stata in Figure 7.

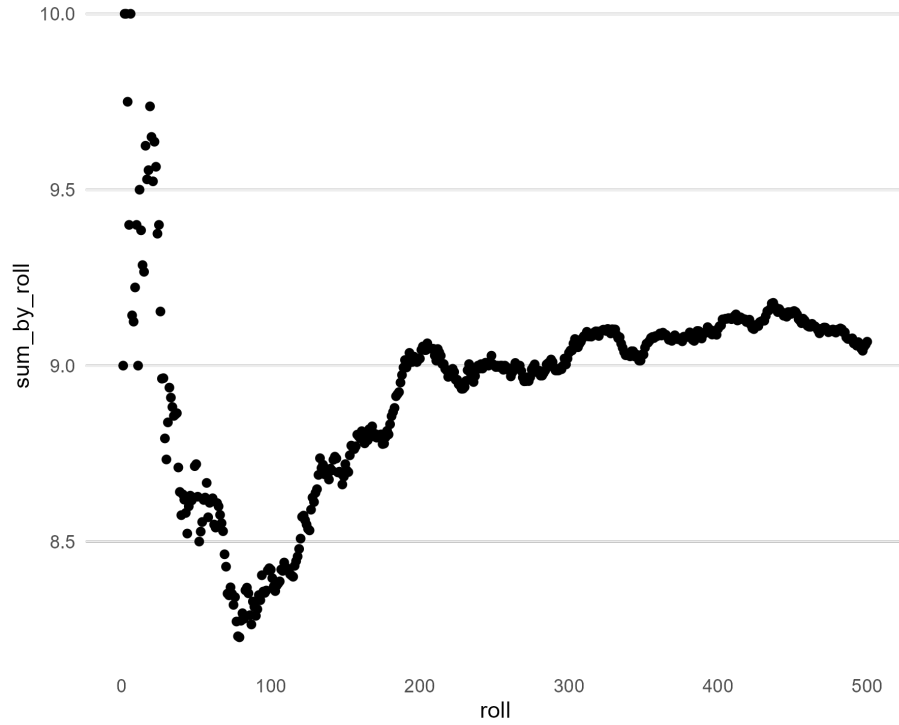

(a) Numerical frequency for the sum of two six-sided die. Figure based on 500 throws. (b) Numerical frequency for the sum of two eight-sided die. Figure based on 500 throws.

**Figure 3:** Combined plots of the simulations.

**Figure 4:** Mean for the sum of two six-sided die. Figure based on 500 throws. Approaches value of 7.02

**Figure 5:** Mean for the sum of two eight-sided die. Figure based on 500 throws. Approaches value of 9.07

**(a)** Mean for the sum of two six-sided die. Figure based on 500 throws. **(b)** Mean for the sum of two eight-sided die. Figure based on 500 throws.

**Figure 6:** Combined plots of the simulations.

**Figure 7:** Stata example
